Marketing Marketing The technical storage or access is required to create user profiles to send advertising, or to track the user on a website or across several websites for similar marketing purposes. Hull Speed 7.5 kn Classic: 6.59 kn The theoretical maximum speed that a displacement hull can move efficiently through the water is determined by it's waterline length and displacement. It may be unable to reach this speed if the boat is underpowered or heavily loaded, though it may exceed this speed given enough power. Read more. Classic hull speed formula: Hull Speed = 1.34 x $\sqrt{\text{LWL}}$ A more accurate formula devised by Dave Gerr in The Propeller Handbook replaces the Speed/Length ratio constant of 1.34 with a calculation based on the Displacement/Length ratio. Max Speed/Length ratio = $8.26 \times \sqrt{\text{Displacement/Length ratio}}$.311 Hull Speed = Max Speed/Length ratio x $\sqrt{\text{LWL}}$ 7.45 knots Classic formula: 6.59 knots Sail Area/Displacement 16.8 16-20: good performance A measure of the power of the sails relative to the weight of the boat. The higher the number, the higher the performance, but the harder the boat will be to handle. This ratio is a "non-dimensional" value that facilitates comparisons between boats of different types and sizes. Read more. SA/D = SA ÷ (D ÷ 64)^{2/3} SA: Sail area in square feet, derived by adding the mainsail area to 100% of the foretriangle area (the lateral area above the deck between the mast and the forestay). D: Displacement in pounds. 16.77 20: high performance Ballast/Displacement 37.8
