Class 8 science chapter 13 question and answer

Class 8 science chapter 13 chemical change and chemical bond question answer.

When the black death ran unbridled through cities in the middle age, no one knew exactly how or why the horrible disease spread. After many generations, we discovered that the fleas of rats and bacteria were guilty. It was a hydrographic time for the power of the science. Later, the science continues to investigate difficult and disconcerting issues every day. However, even with bright minds converging through a worldwide network of computers, we still have all the answers. In fact, some people can argue that we are now learning to ask the truly big questions. What happens to us after we die? How much life appeared on our planet when others seem devoid of any speech? Who, if someone, pulls the ropes of our universe? Is it a Almighty God in Control or Hide Fansical and Mathematical Principles that drive the engine of our existence? Sometimes, after errors, but humans finally stumble into real answers to real issues such as the spreading of diseases. Other times, we keep holding the darkness of our own ignorance and imagining what this really means. In some cases, these issues are so difficult that even the children of our children will probably still be struggling for answers. But mankind will continue to try. Giving his most recent adventures to the eyes, you stung the head of a six-legged rabbit while using a pink hood of Não and shouting, "Gesundheit" at the top of your lungs. You are not sure if this dream means something, unless you may have consumed many hallucinogens during college, or just ate some bad carrots yesterday.Scientists and sleep specialists know when people usually dream. Normally, you dream during the part of the sleepy eye movement (REM) of the sleep cycle. You can see when a person (or even your cat or dog) is experiencing the REM sleep because your zip eyes and for dogs and your bodies can squirm and push too. The electrical patterns of the brain are very active at this stage, as well as when you are awake. But researchers do not know why you dream. It can be a way to reflect or release the stress of everyday life, or even an unconscious way to help you unravel challenging experiences. It could be a way your mind protects from threats and dangers. It can be a biochemical way for your gravel sort, archive or store short or long-term information. Perhaps dreams are a way to reconcile their past and present experiences to prepare and action for the future. No money, dreams are a cornerstone of human experiment. They entertained and haunting us and serve as reminders that our inner world is so deep and strange as the outside world around us. Cancer is an ordinary human terror. Every year, more than half a million people die of various types of Cancer in the United States alone. His familiarity, however, does not make it less scary. Cancer assumes many forms and affects many parts of the body, but the mark of these diseases is the uncontrollable cell replication. Tumors expand and spread, ruining bodies and causing death. Growth happens due to DNA damage. The DNA, of course, provides instructions for all bodily functions, including the growth of the cells. This damage can happen because of certain factors of lifestyle, such as solar exhibition, smoking or exposure to carcinogenic chemical products. Some estimates, more than one third of the tables could be avoided by avoiding habits of câms. However, life choices are just part of the equation. Other factors also play a role. Many people inherit the defective DNA of their parents and have a predisposition for the development of certain types of Câvers, which live totally healthy lives. Miradians and unique genetic makeup of human beings make some scientists doubt that we will have a cure for every type of câcent. There are only many environmental assaults and minute bodily malfunctions for any magic bullet to attack. The good news is that our perspective and treatment treatment CĂ e Nences is evolving. Each year, we understand new aspects of disease. Therapies continue to improve, reducing suffering and adding the quality of life. So although we can never completely defeat the câms, we will continue to beat back, making our lives better, and less terrifying diagnoses. The whole planet would like a better idea of what happens to them after they die. And hey, there are billions of people who already know the answer to that question. Unfortunately, they can not tell us about it because, well, they are all dead. The subject of life after death - or lack of the same - is one of the oldest disturbing issues humanities. Are we all floating for the eternal bliss? The evil among us will be sentenced to the poops of hell? Our consciousness will merely disappear once our bodies expired? Or are we all reincarnated as hypopotous angry or cute cats? Scientist understands the initial stages of death. They know how the human body begins by turning off. As the store's employees, spinning the lights in a megastore after hours of closing, the cells of your body begin to flash, one to one, until your heart is rebran Cesse the activity. What happens after your brain clicks, however, is still a complete mystery. Many people who have experienced almost death and then return to life talk about light or flashbacks for life occurrences or conversations with loved ones who have passed. All these experiences could have biological origins, perhaps stimulated by the lack of biochemical fluctuations of oxygen or wild. The many questions we face about our existence, this is one that never answered. Instead, all we will be left anxious to wonder, looking for a kind of meaning in death. Some may think that we are the unique intelligent life forms in the universe. If that is the case, the universe is unimaginable solitário. Other researchers say that almost no way that the earth is the only thirst for life "There may be to 40 billion of habitan planets à Ć à Ć à Ć òThe a large number of Potential for alien life. There are some necessary requirements to emerge life. There is only one planet needs the right mix of elements and conditions, there is also a fear that originates to live creatures. . Then, of course, these creatures have somehow evolve into beings with intelligence.en for the modern human science, the simplest of the life forms of our planet is still an extremely complex stew of reactions chemical and creature. We do not really understand how they emerge, evolve and survive in an incredibly diverse range of environmental conditions. This makes the discovery, identifying and communicating with much more complicated foreign beings. Despite these challenges, NASA researchers think they could s Find life vestants in the late Proches. More powerful telescopes can be a key to finding this. That is, this life here is only a statistic aberration, an accident of the strangest type. Perhaps this strange panel of a planet is actually a judge of the universe, without instruction and to the contrary from anywhere else, anywhere.yet we know that water and gases and similar elements exist in Many other planets. If we continue to look at and even find a fragment of evidence, such as fossilized remains or bacterial bacterials, it seems more likely than somewhere among the stars that another spy would also be looking at the Cés and Pondering the neighbors somewhere in the universe, also humans have a consciousness of our surroundings and also of us. Our minds have internal conversations and questions about who we are and our purpose in the world. We are as much as we know, the unique creatures with this kind of active conscience. We also have no Where does this conscience come from. In the sights, it is clear, are the central computers of our bodies, controlling the biological functions and helping us to think of all the loops and obstacles of life. Brain scans exhibit how incredibly active our sizers are really, sparking sparkling Constant activity as our 100 billions of nerve squid incessantly trigger, as a compact, but enormously complex digital network. But the rebroiter is not the mind. Electric activity does not explain how a physical substance can create a non-physical condition as a consciousness. Some religions explain the conscience as a gift from God, incorporated into our bodies to guide us through this world. SCENTERS Veer more for biological origins - they see the conscience as a collection of biological processes that construct a more complicated that eventually culminates -Awareness.Scientists determined that animals, such as dogs, almost certainly conscious, but that is a lower (or different) level of consciousness than that of humans.Earth is home to a range Stunning creatures and plants. Pink flamingos fill the skys, elephants HEACHOS STOMP through savannas, and strange fruits and ferns hide in cracks everywhere. We will never know how many different species wander our planet. There are only many. But this does not prevent scientists from trying to determine this indescribable number. Carl Linnaeus realized two and a half are humans that humans needed a system to accompany our planet's sports. He began to classify plants and animals using taxonomic language that named, classified creatures and plants and plants. After work generations, for some estimates that we still represent only 1.5 million species, or about 15% of the total number. This means that most organisms still need adequate description. This is especially true for subvalued and subvalued species, such as fungi, of whom we really describe only 10%. In contrast, we did a good job with our mates mammals, most of whom are already logged in. All numbers are simply statistical hunches, so we can never know if they are precise. Perhaps the biggest concern is that the surroundings seem to disappear a fee more than at any time since dinosaurs have disappeared 65 million years. After all, if the creatures are disappearing in masses, us, human, we could be Next.Human reality is a slippery concept. Anyone who awake from a vivid nightmare knows how he is trapped somewhere between a memory and a dream. These experiences lend credibility for the idea that there are limitations to our senses. Perhaps our eyes, ears and sense of smell does not tell all the story about reality around us. Things and people in our lives are merely illusions. How do we know that any of these objects and creatures really exist? Perhaps they are constructed from our own internal mechanisms, generated by our subconscious for unknown purposes. The universe could be a hologram, a creation of "matrix" style computers intended to hold our minds and enslaved us to an evidence.Scientists and physics are not sure that we will never understand the nature of reality . The deeper we deepen in physics, the stranger that the mechanic of our universe has become. We continue to discover new fundamental particles and forces, from molecules to an matrix, which drive our bodies and our world. It is entirely as possible that the universe could be done from tens or thousands of dimensions we will never experience in any direct way. It is improbable that the scientific rabbit hole we have buried will end. It does not matter how intelligent our collective spy becomes, reality will always be an abstraction that we can never hold. Our planet is filled with trees, gramins, birds and bees. It is also filled with bacterial numbers. All this is life, and all this reproduces to keep your type alive. But how in the world life started first? A mass of cells charged from an inert collection of organic moloeps to a be babbling and, sometimes even intelligent? The short answer is: we do not know exactly how life originated. There is a chance that 4 billions of years ago, the aliens fell a few microbes and let left Run wild. And, of course, many religions have supernatural explanations for the origins of life. Many scientists think that life is a natural progression for the planets that present the necessary ingredients for biology, such as carbon, hydrogen, oxygen and other key blocks. With the right faar - say, a radius - these belts are slowly developed in the cell walls and DNA that are suitable for reproductive life. Researchers are continuously performing experiments like this in laboratories, in the hope of broadening the transula to make life tent as they can, is a mystery like these pieces of non-alive parts gathered in creatures real alive. It could be that we are still ignorant for the features that really define life. Or maybe we are blind to the principles of the physics that actually do life tick. No matter the case, the search for life sources will continue, without a doubt, will continue for a long time. Then the concepts of scientific fiction vain, the trip in time is one of the most captivating. It is difficult not to ask how it would be to zip back to the story to witness a Roman battle in action. Maybe it's even more intriguing to ponder what our world would be like if you could overload 1,000 years for the future. As it ends, the trip in time may not be fiction. It may be that we still do not let us make it work for us. One possibility is wormholes, which are bridges of a spy that could help people go through time and space. If you could violate an opening in a wicker hole, you could theoretically enter and then end up on the other side of the galley in a different place and time. We can try to travel to the speed of light, at what point your world decreases in comparison with what you get back. Our current science says that nothing can move so fast as light, but might, and even if we could rip our bodies apart.maybe we could orbit black black holes, who have this incredible gravitation They really decrease the time. Going out by a black hole and his time experience would be approximately reduced in life on earth. If you returned 10 years later by your perception, your family would have between 20 years in this time. Or maybe I could use thymical ropes, the so-called cracks in the universe, to navigate time. These strings (which also sometimes are loops) have a lot of mass that can actually cause spatial time around them float. Manipulating any of these scenarios can grant us the power to finally realize the trip in time. Even we can discover the science, but there are numerous paradoxes that can make time revealable or frankly dangerous. So, for now, traveling in time is still simply the material of books and movies. When you look up on a dark night and see the uncontrollable stars. "" Scattered all over the sky, it is easy to think of the universe as infinite. Or maybe you see these illuminations as similar to the shine stars on the ceiling of your room, just beautiful decorations to avoid, a high ceiling, but without skirt. Either way, the science can not really tell us, but the universe is infinite or finite. As with everything else, the researchers have theories. After analyzing the maps generated by observations made with Baryon's spectrician survey (boss), a super-powerful telescope in the new Mexico, a group determined that the universe has a superficial plan plan. The research was based on observations of "only" 1.2 million gallsaps, which is a fall in the universal bucket, but it is a strong lane that our universe is not in the form of a sphere . So, is this infinite plancity? It is impossible to say. A reigning thought is that Big Bang is causing the universe to constantly expand more than the speed of light. Because we can not see the speed of We will never know if there is an advantage for the universe. We probably have to spend our lives wondering about the true nature of the size of the universe. universe. A mystery, like so many others, which is overflowing from a captivating fascinum that attracts our minds, but never offers any real answers. If you are struggling with how great the universe can be or how life originated from Earth, our existence is full of bizarre turnarounds of nature that we can not explain and never understand. These questions can bother us and give us in our entire lives - but they are also an essential part of the human experience.Eginally published: April 6, 2016, easy for modern people to look back Your ancestors with more than a little desdÉ. Living in caves, really? Where is your dignity, monkey men? But most do not understand that 100 years from now on, our grandchildren goes to look at us with the same kind of light sympathy, thinking of us as primitive and ignorance. The evolution of the human science and knowledge has this kind of effect. So, perhaps in 20 or 50 years, this list of not answered questions will seem quaint and appeal. It is more likely that, however, that at least some of these questions will endure the time test.Related StoriesBreus, Michael J. "Why do we dream?" Psychology today. February 13, 2015.
